## Introduction

**Non-invasive imaging gains interest in the evaluation of novel synthetic scaffolds in bone tissue engineering as an alternative approach to the clinical gold standard treatment (autografting)[1]. Herein, we employ collagen-based scaffold materials as bone implants labelled with magnetic nanoparticles (MNPs)[2,3] (MCF) and with $^{99m}$Tc[4] (CF) for *in vitro* detection of enzymatic activity of metalloproteases[5]. This labelling will further permit to *in vivo* follow the fate of these new bone grafts supplemented with cells, using MRI, nuclear imaging and CT[6].**

## Methods

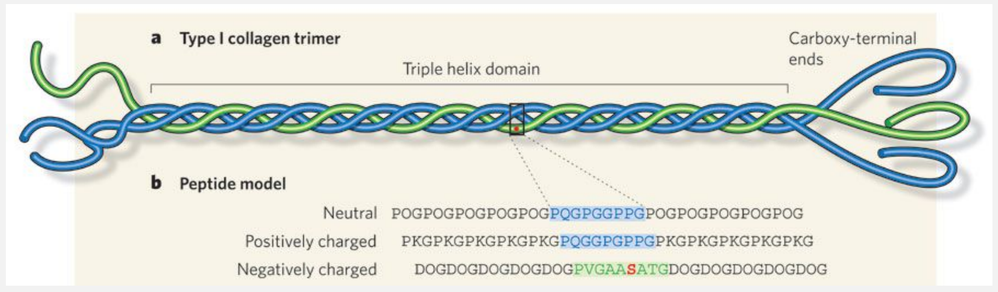

**Fig. 1: Structure of type I collagen, a heterodimer protein composed of two α1(I) polypeptide chains and one α2(I) polypeptide chain, which spontaneously form a triple helix scaffold at pH=7 and at 37º C, manually extracted from rat tail tendon, at a final concentration of 4.0 (mg/ml) in acetic acid.**

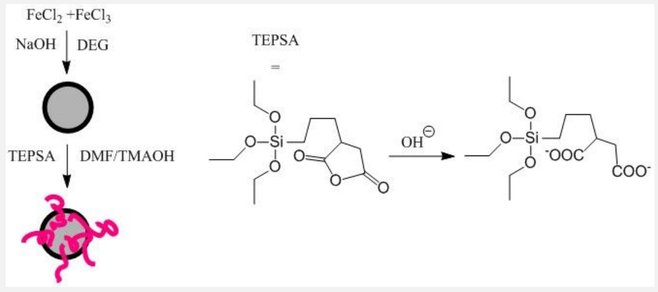

**Fig. 2: Synthetic route to obtain MNPs: i) co-precipitation of iron salts in basic organic medium; ii) stabilization of the iron oxide cores by means of TEPSA treatment [2]**

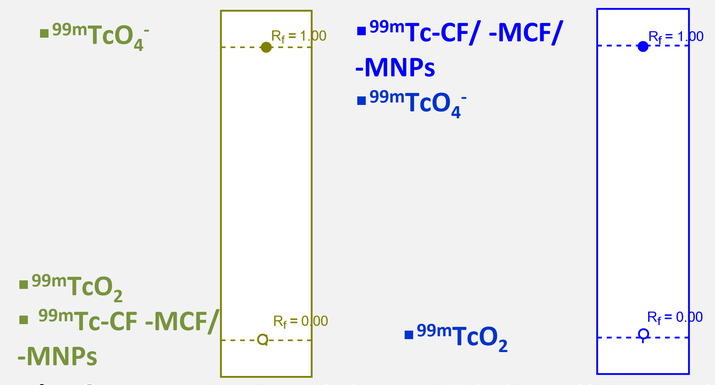

**Fig. 3: Determination of the radiolabeling efficiency of both forms of collagen (CF, MCF) and of MNPs and of the radiochemical purity performed by ITLC – SG using acetone and a mixture of pyridine: acetic acid: water (3:5:1.5) as the mobile phases[4]**

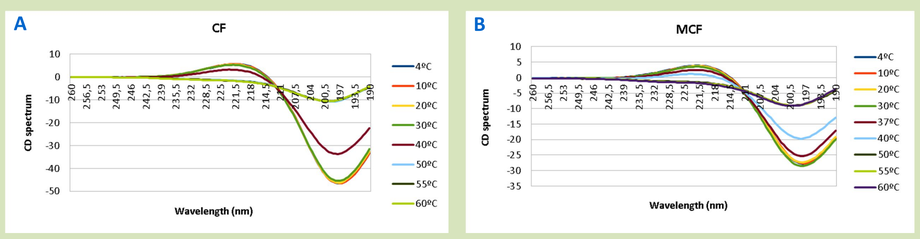

**Fig. 4: Variation of CD spectrum of unmodified collagen (CF) (A) and of MNP-labelled collagen (MCF) (B) as a function of the temperature. The min and max values for CF were observed at 198.06 nm ±1.14 and at 223.25 nm ±2.25; The min and max values for MCF were observed at 198.5 ±1.14 and at 222.77 ±1.73 respectively. The collagen samples concentration was 0.1 mg/mL in acetic acid.**

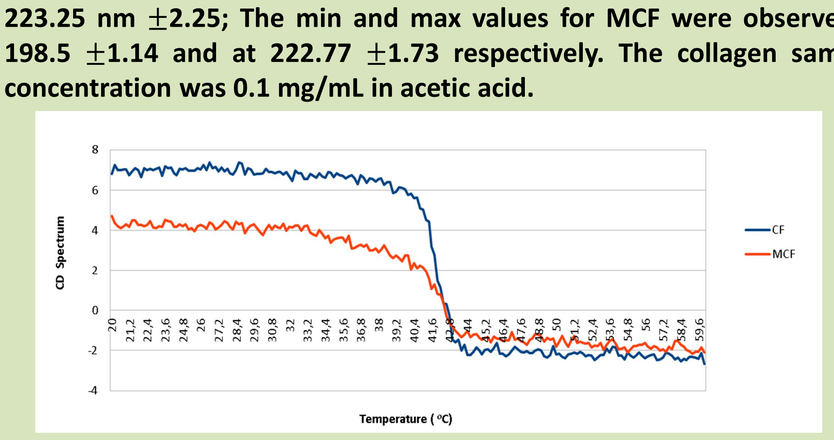

**Fig. 5: Comparative CD spectrum for CF and MCF at 221 nm. Melting effects were observed at temperatures higher than 40º C for both samples. Td values were observed at 42,7º C and 42º C for CF and MFC respectively. The collagen samples concentration was 0.1 mg/mL in acetic acid.**

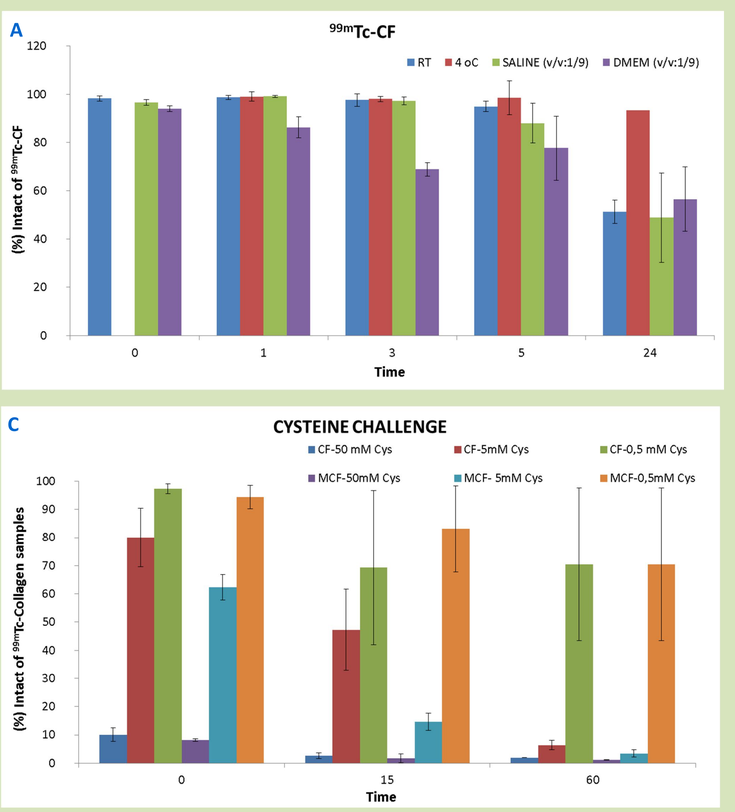

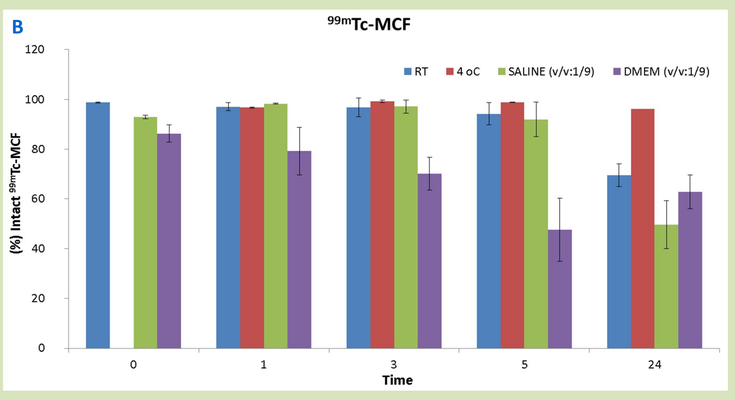

**Fig. 6: Stability study of: (i) $^{99m}$Tc-labeled CF (A) MCF (B) in relation to temperature (RT and 4 ºC); in the presence of an isotonic solution (NaCl (0.9 (%)); culture media at 37 ºC; (ii) both labelled collagen samples (C) in the presence of excess amount of cysteine.**

| | (%) Collagenolytic radioactivity (CF) | (%) Collagenolytic radioactivity (MCF) |
|---|---|---|
| t=0 | 21.9±7.8 | 11.6±3.8 |
| t=2h | 61.2±26.1 | 44.0±1.1 |
| t=4h | 87.2±9.9 | 87.4±5.5 |

**Table 1: Collagenase assays following incubation of collagenase (1.0 mg/mL) with the radiolabeled collagen preparations used as substrate at 37ºC.**

**Fig. 7: *In vivo* MRI data collected on Albino Swiss Webster mice injected with: $^{99m}$Tc-labeled MNPs (three images aligned to the left side); MNPs (three images aligned to the right side) by a 9.4T Biospec (Bruker) ; Circles are drawn around the liver (green circle), spleen (yellow circle) and regions selected around the bone (yellow area)**

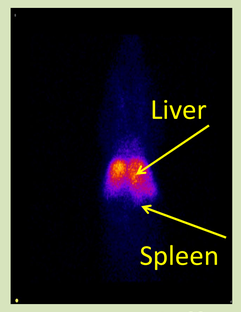

**Fig 8. Planar γ-imaging of $^{99m}$Tc-labeled MNPs (100ul, 100uCi or 3.7MBq) at 1h p.i. in Albino Swiss Webster mice by a NanoSPECT/CT system (Mediso)**

## Conclusions

- ✓ **CD curves were similar for collagen free (CF) and magnetically modified collagen (MCF). Denaturalization was clearly when <40 ºC.**
- ✓ **No significant difference was observed between CF and MCF monitoring the radiolabeling stability tests.**
- ✓ **A linear increase in collagenolytic activity occurred over time for both radiolabelled collagen samples.**
- ✓ ***In vivo* uptake of labeled or non-labeled MNPs was significant in the mononuclear phagocytic system.**
- ✓ **Colorimetric experiments of collagen degradation after being exposed to collagenase over time are ongoing.**
- ✓ **Animal models are now established and imaging results encourage in vivo monitoring of MCF or cell/MCF constructs-induced inflammation, enzyme activity and bone formation in mouse models with calvarium bone defects using MRI and SPECT/CT[6].**
